

# THE He I 10830 Å TRIPLET:

## A TOOL FOR UNDERSTANDING CHROMOSPHERIC MAGNETISM

Rebecca Centeno  
(High Altitude Observatory)

# Introduction

CHROMOSPHERE

Wedemeyer-Böhm et al. 2008

# Chromospheric diagnostics

Some typical chromospheric indicators:  
 $H_\alpha$ , Ca II H & K, Ca II IR triplet, Na D,  $Ly_\alpha$

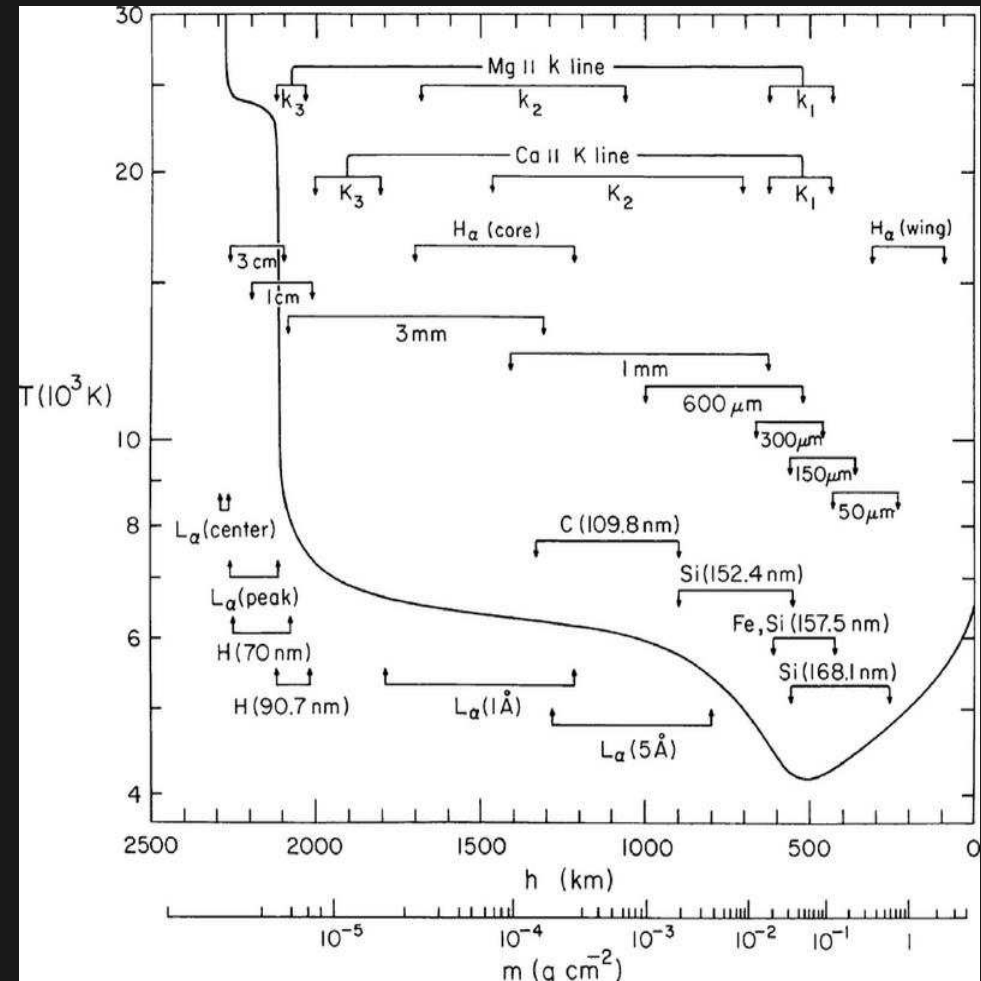

FILTERGRAMS – crosstalk among opacity,  
 Doppler effects, temperature sensitivity.  
 Photospheric leakage

Need for **full spectral profile**

PROXY MAGNETISM – crosstalk between  
 temperature, magnetic field

Need for **full Stokes vector**

LINE FORMATION -- very **broad regions**  
 of the atmosphere in conditions that  
 are very far from LTE

Spectral line forming regions,  
 Vernazza et al. (1990)

# He I 10830 Å

## Formation mechanism

Under normal  
chromospheric  
temperature conditions  
triplet states are not  
sufficiently populated

He II —————

Singlets

Triplets

He I

# Formation mechanism

Under normal chromospheric temperature conditions triplet states are not sufficiently populated

Coronal EUV light triggers the PR mechanism ...

He II \_\_\_\_\_

Singlets      Triplets

EUV

He I

1st IP = 24.6 eV

# Formation mechanism

Under normal chromospheric temperature conditions triplet states are not sufficiently populated

Coronal EUV light triggers the PR mechanism ...

Which leads to an **overpopulation of the triplet states**

1st IP = 24.6 eV

# Zeeman, Hanle and scattering polarization

## Zeeman Effect

# Zeeman, Hanle and scattering polarization

## Scatt. Polarization ( $B = 0$ )

## Hanle Effect ( $B \neq 0$ )

The presence of a magnetic field breaking the symmetry modifies the population imbalances and the quantum coherences between the magnetic sublevels, resulting in a net change and a rotation of the plane of polarization.

See review by Trujillo Bueno (2005)

## First the bad things..

Spatial correlation with **coronal activity**. This means that it has barely any opacity in the quiet Sun. Warped layer of formation.

Proper forward modeling requires dealing with **non-LTE problem**: solving radiative transfer and statistical equilibrium equations consistently, including EUV coronal irradiation

The interpretation of **scattering polarization** (modification of sub-level population due to anisotropic illumination) and the **Hanle effect** is even more complicated

## Now the good things...

Forms in a thin layer at the **top of the chromosphere** with NO influence from the photosphere

Magnetically sensitive – Zeeman **splitting goes with  $\lambda^2$**

There is a **photospheric line** nearby (Si I 10827 Å) – simultaneous and cospatial measurements of the photosphere and chromosphere

For low-lying structures it is easy to **interpret** signals with a simple **Milne-Eddington** inverter (in sunspots, plage, network..) -- Reliable magnetic field diagnostics!

It is sensitive to **atomic level polarization** and its modification through the **Hanle effect** -- for high lying structures (prominences, filaments, spicules) that are anisotropically illuminated allows to measure magnetic fields as weak as mG to a few gauss. Difficult interpretation but inversion codes already available!!

# Waves in magnetic structures

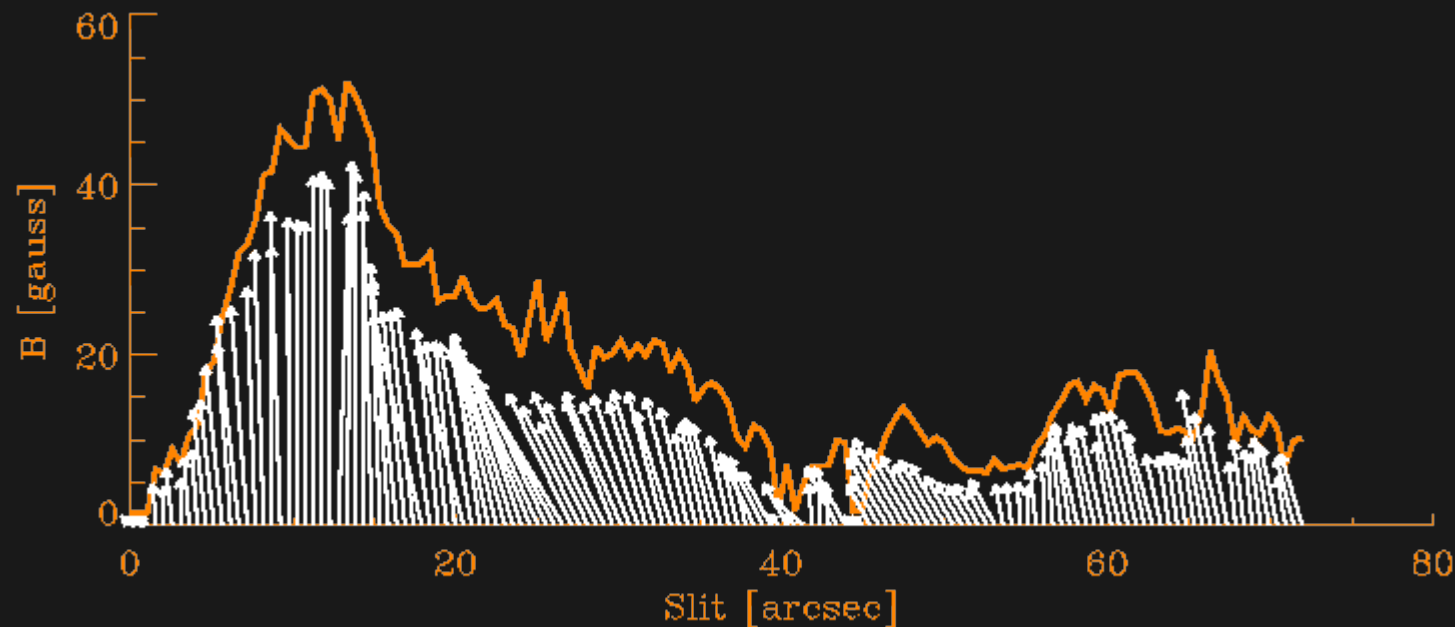

(Centeno et al. 2009)

- \* The He I 10830 multiplet is able to "see" the chromospheric dynamics of magnetized regions
- \* It can trace velocity oscillations and magnetic field configuration and evolution
- \* Waves provide clues about the thermodynamical and magnetic structure of the atmosphere

# Spicules

# Spicules

- The *role of magnetic fields* in the formation and dynamics of spicules?
- The *properties* of these fields
- How much do they *change along the length* of the spicule

# Quiescent Prominences

Trujillo Bueno et al. 2002

Merenda et al. 2006

# AR Filaments (on disk)

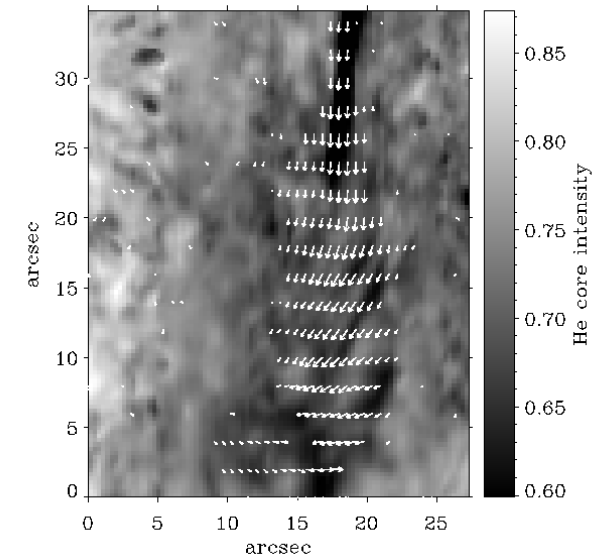

Continuum intensity

Chromospheric LOS  
magnetic field (He 10830)

He core image and mag.  
field azimuth

(C. Kuckein et al. 2009)

# AR Filaments (on disk)

Continuum intensity

(C. Kuckein et al. 2009)

Inversions reveal **magnetic fields** as strong as **750 G** in the Chromosphere and aligned with the rope-like structure

## Into the future

The He I 10830 Å multiplet is a great tool for diagnosing chromospheric magnetic fields:

- \* It has no influence from the photosphere
- \* It works in a variety of different scenarios
- \* It's relatively easy to interpret its polarization signals with M-E in many cases
- \* When we can't do that, we can now resort to other inversion codes that account for scattering polarization and the Hanle effect

You know what would be REALLY AWESOME?
